ABSTRACT

The tuberous sclerosis complex is a multisystem disorder affecting children and adults. The association between abdominal aortic aneurysm and tuberous sclerosis is rare. We present 3-year-old girl with a pulsatile abdominal mass in the pediatrician’s medical review. An abdominal evaluation showed a 6cm infrarenal abdominal aortic aneurysm. The patient underwent open repair with a 14-mm Dacron tube graft. The histological examination revealed connective tissue proliferation, fibrosis, and calcification of the aortic wall. Frequent follow-ups with ultrasounds showed no alterations. Due to the high risk of rupture, early surgical repair is the first-line therapy.

Introduction

Tuberous sclerosis (TS) is an autosomal dominant disease arising from genetically programmed hyperplasia of ectodermal and mesodermal cells and manifested by a variety of lesions in the skin, central nervous system, heart, kidney, and other organs, affecting children and adults [1]. The association between abdominal aortic aneurysm (AAA) and tuberous sclerosis is rare. Diagnostic noninvasive vascular evaluation must include ultrasound, magnetic resonance angiography and computed tomography [2, 3]. We present 3-year-old girl with a pulsatile abdominal mass in the pediatrician’s medical review. An abdominal evaluation showed a 6cm infrarenal AAA. We present our experience on the open repair of AAA in a girl with TS.

Case Report

A 3-year-old girl with normal growth and development with history of partial seizures and no significant medical history nor a familiar history of TS, was found a pulsatile abdominal mass during the endocrinologist review for premature thelarche. On admission her height was 91cm, body weight 12kg, heart rate 130 bpm, body temperature 36.7ºC and blood pressure 94/63. Blood examination did not reveal any abnormalities. The brain magnetic resonance demonstrated calcified intracranial lesions (Figure 1). Cardiac evaluation revealed a myocardial mass in the papillary muscle (Rhabdomyoma). Abdominal computed tomography showed a big infrarenal saccular aneurysm measuring 68.1 x 52.5 x 54.6 mm (Figure 2). The aortic bifurcation was not involved. Surgical intervention was performed through a midline laparotomy revealing a 50 mm infrarenal aneurysm (Figure 3). With 1mg/kg IV heparin the girl underwent surgery consisting of infrarenal aorta aortic interposition of a 14mm Dacron tube graft (Figure 4), the rest of the abdominal aorta and the aortic bifurcation were left with normal diameters (7-8 mm). No complications were reported during the procedure. Her postoperative course was uneventful, and the patient was discharged on the fifth day. The girl recovered rapidly and returned to normal life. Anti-platelet therapy was used after AAA repair because of the large size of the graft. Histological examination of the excised aortic wall revealed fibrosis and calcification. Frequent follow-ups with ultrasounds showed no alterations.

Discussion

Tuberous sclerosis complex is a genetic disorder with autosomal-dominant inheritance; it is common in children. A variety of organs is frequently affected. The association between TS and aortic aneurysms is rarely observed, however, when presented it can be potentially risky. Aortic aneurysms in patients with TS are frequently missed, the diagnosis is usually incidental or after aneurysm rupture.

Open repair with interposition of an aorta aortic graft is the most direct surgical approach to treat this condition. In children, it is recommended the largest possible graft to allow proper vascular growth. Oversizing graft is one of the most important techniques [4-8]. Anticoagulation or anti-platelet therapy is difficult to conclude if it is necessary to use it, due to limited experience reported [3]. However, in our center based on our experience in adults’ cases undergoing Dacron vascular tube interposition surgery and Blalock-Taussig Shunt and Rastelli conduit surgeries in children, we propose following anti-platelet therapy for 1 year until the graft heals. Long-term follow-up is mandatory after this surgical intervention.

In conclusion, patients with TS should be screened for aortic disorders in order to rule out aortic aneurysms due to the high risk of rupture. This condition should be treated by early elective open repair surgery, performed in specialized center. Long-term follow-up is mandatory after surgical intervention.

Consent

The patient’s parents gave written permission for anonymous publication of patient data and medical images.
